## ABSTRACT

The success of breeding program for improvement any crop depends mainly on the available background of the inheritance of the studied traits to be selected. This study was carried out during 2018/2019, 2019/2020 and 2020/2021 grown seasons at the experimental farm of Sakha Agricultural Research Station, Agricultural Research Center, Egypt to estimate the effect of genetic parameters controlling yield and yield component traits in addition severity of leaf rust and powdery

\*Corresponding author: E-mail: barley\_breeder@yahoo.com;

mildew disease infection. Six generations ( $P_1$ ,  $P_2$ ,  $F_1$ ,  $F_2$ ,  $BC_1$  and  $BC_2$ ) model was used. Results indicated that, mean effect ( $m$ ) was highly significant in all evaluated crosses for all studied traits. The relative importance of additive and dominance effects differed from trait to another in each cross. For epistatic components, dominance  $\times$  dominance interaction effects were more effective than other components in most studied traits. Significant or/and highly significant values in desirable direction of heterosis compared to mid and better parent were obtained from most studied crosses in yield and its attribute traits, but it found over mid parents only for cross no.1 in leaf rust and crosses no. 1 and 2 in powdery mildew infection. The estimation of broad-sense heritability showed high values for studied traits and crosses, while narrow-sense heritability and genetic advance from selection ranged from low to medium in most crosses for the agronomic traits, while it ranged from low to high for leaf rust and powdery mildew infection. Finally, the results of this study recommended the barley crosses no. 4 for improve yield potential and resistant to leaf rust and cross no. 5 to improve resistance to powdery mildew, where it had high genetic advance associated with high heritability.

**Keywords:** Barley; improvement; genetic components; disease resistance; yield.

## 1. INTRODUCTION

Barley (*Hordeum vulgare* L.) is considered as one of the great important crop species grown in the world [1], ranking fourth important crop after wheat, rice and maize [2] with a great adaptation potential. Barley used for different purposes such as human food in few countries, animal feeding in wide areas around the world and malt industry. Enhancement of yield potential considered as an important goal in barley breeding program [3]. Barley considered as dry, cold, salt-tolerant and well adapted crop to low-input environmental conditions and climatic change [4]. Breeding cereal crops for high productivity, good quality and resistant to common disease are important to satisfy food demand of this world. Powdery mildew and leaf rust diseases caused a loss on yield in barley. Powdery mildew (PM) caused by *Blumeria graminis* f.sp. *hordei* Em. Marchal (Bgh) is a widespread fungal disease of many mono and dicotyledonous plant species. In moderate temperate and humid climate, the loss of productivity due to powdery mildew can reach up to 30%, at an average of 5–10% [5]. Leaf rust caused by *Puccinia hordei* is one of the most serious constraints in barley production in many barley-growing regions. Yield losses due to barley leaf rust may be up to 60% in susceptible varieties [6]. However, the mean yield losses of barley caused by barley leaf or stem rust often reach 10–25% [7]. Due to the great problems that result from the use of fungicides and their negative effects on the environment and health, the use of resistance cultivars is considered an environmentally benign and effective way to control these diseases [8]. Generation mean analysis considered as important method for genetic analysis of quantitative traits [1]. The

present study was conducted to estimate the effect of genetic parameters controlling yield and its attribute traits in addition the infection of leaf rust and powdery mildew diseases in six barley cross combinations.

## 2. PLANT MATERIALS AND METHODOLOGY

### 2.1 Genetic Materials and Experimental Design

The current study was carried out during 2018/2019, 2019/2020 and 2020/2021 growing seasons at the experimental farm of Sakha Agricultural Research Station, Agricultural Research Center, Egypt. Experimental material was the six generations *viz.*,  $P_1$ ,  $P_2$ ,  $F_1$ ,  $F_2$  and two backcrosses ( $BC_1$  and  $BC_2$ ) relating to six crosses involving three sensitive local cultivars (Giza 123, Giza 126 and Giza 125) and two resistant exotic lines (Line-1 and Line-2) (Table 1).

The selected parents were crossed in 2018/2019 growing season to produce  $F_1$  hybrids of six barley crosses; 1 (Giza 123  $\times$  Line-1), 2 (Giza 126  $\times$  Line-1), 3 (Giza 125  $\times$  Line-1), 4 (Giza 123  $\times$  Line-2), 5 (Giza 126  $\times$  Line-2) and 6 (Giza 125  $\times$  Line-2). In the second season (2019/2020) the hybrid seeds were sown and  $F_1$  plants of each cross were backcrossed to their respective parents to produce the two backcrosses ( $BC_1$  and  $BC_2$ ) seeds. At the same time, some of the  $F_1$  plants were selfed to produce  $F_2$  seeds. In the third season (2020/2021), the obtained seeds of these populations, *i.e.*  $P_1$ 's,  $P_2$ 's,  $F_1$ 's,  $F_2$ 's,  $BC_1$ 's and  $BC_2$ 's for the six studied crosses were sown

in the field using a randomized complete blocks design (RCBD) with three replications. Each plot was about one row for each P<sub>1</sub>, P<sub>2</sub>, F<sub>1</sub>, six rows for F<sub>2</sub> and two rows for each of BC<sub>1</sub>, BC<sub>2</sub> in each replicate, rows were 2.5m long, 25cm width and the space from plant to plant in a row was 10cm. All agricultural practices were followed according to the growing barley recommendations. The experiment was grown under natural infection in the field and the experiment was surrounded with highly sensitive cultivars for both diseases as spread disease cultivars.

## 2.2 Data Recording and Measurements

Data were recorded on 30 individual guarded plants in each P<sub>1</sub>, P<sub>2</sub> and F<sub>1</sub>, 90 plants in each BC<sub>1</sub> and BC<sub>2</sub> and 300 plants in each F<sub>2</sub>. Plant height (cm), spike length (cm), number of grains/spike, number of spikes/plant, 100 grain weight (g), grain yield/plant (g) in addition to the reaction of leaf rust and powdery mildew disease. Leaf rust severity was recorded as stated by Peterson et al. [9]. While powdery mildew severity was measured as scale 0-9 at the growth stage 10.5 stated by Lagrge [10] and Sarri and Prescott [11]. Heterosis percentage (%) calculated as the increase of F<sub>1</sub> over the mid- and better parent values.

## 2.3 Statistical and Genetic Analysis

- Scaling test was performed as stated by Mather [12] to identify the presence of non-allelic interactions.
- Generation mean analysis was performed as stated by Mather and Jinks [13].
- Types of gene effects were calculated as stated by Gamble [14].
- Broad (h<sup>2</sup>b) and narrow senses (h<sup>2</sup>n) heritability were estimated as stated by Allard [15] and Mather [12].

- Expected genetic advance from selection (GA) was estimated as stated by Johnson et al. [16] formulae.
- Predicted genetic advance from selection was expressed as percentage of F<sub>2</sub> mean (GA%) was estimated as stated by Miller et al. [17].

## 3. RESULTS

### 3.1 Mean Performance

The calculated means and variances of the measured traits in the evaluated crosses for the tested populations P<sub>1</sub>, P<sub>2</sub>, F<sub>1</sub>, F<sub>2</sub>, BC<sub>1</sub> and BC<sub>2</sub> are presented in Table (2a and b). Results indicated that, F<sub>1</sub> mean values were higher than average of the two parents and favorable parent for yield and related traits in the all evaluated crosses except for plant height in cross no. 4 in the comparison to mid and high parents, spike length in cross no. 6, grains number/spike in cross no. 2 and 100 grain weight in crosses no. 2 and 5 in comparison to better parent.

For the two-barley disease, F<sub>1</sub> mean values showed desirable values in negative direction in cross no. 1 for leaf rust and in crosses no. 1 and 2 for powdery mildew, where it showed values less than average of the two parents. The data of F<sub>1</sub> performance reflected the presence of heterotic effect in most studied crosses and traits. Mean values of the F<sub>2</sub> population were in-between the two barley parents and smaller than F<sub>1</sub> mean values in most barley crosses for and traits reflecting the importance of non-additive components of genetic variance for the calculated traits. However, the two populations (BC<sub>1</sub> and BC<sub>2</sub>) mean values varied in each trait tended towards the mean of its recurrent parent.

### 3.2 Heterosis, Inbreeding Depression and Potence Ratio

Heterosis over both mid and favorable parent values are presented in Table (3a and b). For the agronomic traits (yield and its related traits), results reflected significant heterosis over both mid and better parents in favorable direction that were found for all traits and crosses except for cross no. 4 over mid and better parents for plant height, cross no. 6 for spike length, cross no. 2 for number of grains/spike and crosses no. 2 and 5 for 100 grain weight where it showed negative or insignificant values. Concerning barley diseases, highly significant and negative heterosis over mid parents in desirable direction were found for cross no. 1 for leaf rust and cross no. 1 and cross no. 2 for powdery mildew.

Results presented in Tables 3a and b reflected significant and positive values of inbreeding depression for spike length, spikes number/plant

and 100 grain weight in all evaluated crosses except of cross no. 2 for spikes number/plant, number of grains/spike in cross no. 5 and for grain yield/plant in crosses no. 1, 2 and 6. For barley disease infection, significant and favorable values for inbreeding depression were noted for studied disease in barley crosses no. 1 and 2, while the other barley crosses of powdery mildew showed significant and positive values. On the other hand, the rest crosses reflected insignificant values which considered as a desirable value for these traits.

For the agronomic traits, potence ratio exhibited over dominance (values mor than unity) for all evaluated crosses and traits except for spike length in cross no. 6 and 100 grain weight in crosses no. 2 and 5. For barley disease traits, the values of potence ratio were smaller than the unit reflecting partial dominance for all evaluated crosses for the two barley disease.

**Table 3a. Heterosis, inbreeding depression and potence ratio in the evaluated barley crosses for plant height, spike length, number of grains/spike and number of spikes/plant**

### 3.3 Scaling Test and Type of Gene Action Estimates

Scaling test and six parameters were calculated using the collected data as stated by Gamble procedure [14]. At least, one of the scales (A, B and C) should be significant. However, the significance of any one of the scales reveals the presence of non- allelic interaction. Data of all evaluated crosses for all measured traits exhibited the presence of non-allelic interaction (Table 4a and b).

The six parameter estimates, i.e. means (m), additive (a), dominance (d), additive x additive (aa), additive x dominance (ad) and dominance x dominance (dd) are presented in Table 4a and b. From finding of six-parameter model it was found that, mean effects for all studied traits in the all evaluated crosses were highly significant, indicating that these traits are quantitatively inherited.

Additive gene effects (a) were quite small in effects compared to the dominance gene (Table 4a and b). Positive (favorable direction) and significant results of the effects of additive gene

were found in cross no. 2 for plant height, cross no. 6 for spike length and grains number/spike, cross no. 5 for spikes number/plant and grain yield/plant and cross no. 3 for 100 grain weight.

Dominance (d) gene effect estimates reflected significant values and positive for the evaluated agronomic traits and crosses except in cross no. 4 for spike length and grain yield/plant, crosses no. 2, 3 and 4 for grains number/spike, cross no. 2 for spikes number/plant and cross no. 5 for 100-grain weight. For disease traits, effects of dominance gene were significant and negative for leaf rust in all evaluated crosses except in cross no. 4 and for powdery mildew in crosses no. 1, 2 and 4 (Table 4a and b).

For additive x additive (aa) types of epistasis, significant and positive values (desirable direction) for the agronomic traits were found for plant height in all evaluated crosses except in barley cross no.1, spike length in crosses no. 3 and 6, grains number/spike in crosses no. 1 and 6, spikes number/plant in crosses no. 1, 3, 4 and 6, 100-grain weight in all evaluated crosses except in cross no.5 and grain yield/plant in crosses no. 1, 2 and 6.

	6	-2.04**	-0.51	-0.99	4.37**	1.84**	-0.39	-1.56	-0.76*	4.11**

(\*) and (\*\*) significant at 0.05 and 0.01 levels of probability, respectively.

For disease traits, the effects of additive  $\times$  additive gene reflected desirable values for powdery mildew in crosses no. 2 and 4 (Table 4a and b), indicating that these traits had accumulating genes and selection for its development could be effective. Concerning additive  $\times$  dominance (ad) types of epistasis, desirable data (significant and positive) were detected for plant height in cross no. 3, grains number/spike in crosses no. 1, 2, 3 and 6, while significant and negative finding were recorded for powdery mildew in crosses no. 4, 5 and 6.

For dominance  $\times$  dominance (dd) epistasis gene effects, significant or highly significant and positive valued were detected for spike length in crosses no. 1, 3 and 5, grains number/spike in crosses no. 3, 4 and 5, spikes number/plant in crosses no. 2 and 5, 100-grain weight in cross no. 5 and grain yield/plant in cross no. 2. While the other crosses showed insignificant and/or significant undesirable values (Table 4a and b). These results confirm the important role of dd gene action in the genetic system.

### 3.4 Heritability Estimates and Expected Genetic Advance from Selection

The assessment of heritability in both broad ( $h^2b$ ) and narrow ( $h^2n$ ) sense and expected genetic advance from selection for barley studied traits are presented in Table (5). Heritability estimates in broad sense were relatively high for all studied traits in all crosses. Broad sense heritability for plant height ranging from 92.83% in cross 4 to 96.23% in cross no. 2, for spike length ranged from 92.31 in cross no. 3 to 95.49% in cross no. 2, for grains number/spike ranged from 93.68% in cross no. 3 to 95.38% in cross no. 2, for spikes number/plant ranged from 95.47% in cross no. 3 to 96.89% in cross no. 4, for 100 grain weight ranged from 93.54% in cross no. 1 to 97.71% in cross no. 5, for grain yield/plant ranged from 91.08% in cross no. 4 to 93.60% in cross no. 6, for leaf rust infection ranged from 98.28% in cross no. 1 to 98.83% in cross no. 2 and for powdery mildew infection ranged from 94.93% in cross no. 1 to 97.93% in cross no. 6.

Heritability estimates in narrow sense were low to high and ranging from 19.15% in cross no. 1 to 38.16% in cross no. 6 for plant height, from 30.99% in cross no. 5 to 51.40% in cross no. 4 for spike length, from 26.90% in cross no. 2 to 34.95% in cross no. 1 for grains number/spike, from 22.68% in cross no. 4 to 39.57% in cross no. 5 for spikes number/plant, from 12.46% in

cross no. 2 to 31.21% in cross no. 5 for 100 grain weight, from 14.96% in cross no. 2 to 36.14% in cross no. 5 for grain yield/plant, from 15.57% in cross no. 4 to 63.44% in cross no. 5 for leaf rust infection and from 17.20% in cross no. 5 to 95.57% in cross no. 6 for powdery mildew infection, which indicate that these traits were greatly affected by additive and non-additive effects.

The expected genetic advance from selection at 5% selection intensity of  $F_2$  mean (GA%) ranged from 3.67% in cross no. 1 to 7.68% in cross no. 6 for plant height, from 12.60% in cross no. 5 to 17.20% in cross no. 4 for spike length, from 6.79% in cross no. 3 to 10.11% in cross no. 5 for grains number/spike, from 20.42% in cross no. 4 to 32.02% in cross no. 5 for spikes number/plant, from 4.04% in cross no. 1 to 8.54% in cross no. 5 for 100 grain weight, from 13.0% in cross no. 2 to 34.04% in cross no. 5 for grain yield/plant, from 29.73% in cross no. 2 to 107.23% in cross no. 5 for leaf rust infection and from 19.18% in cross no. 5 to 118.30% in cross no. 6 for powdery mildew infection.

## 4. DISCUSSION

Data in Table 2a and b showed mean and variance of the six studied population ( $P_1$ ,  $P_2$ ,  $F_1$ ,  $F_2$ ,  $BC_1$  and  $BC_2$ ) for the measured traits. Results indicated that, the mean values of  $F_1$  were higher than mid and favorable parent for most measured traits in most evaluated crosses which indicate the presence of heterosis. Also, variances of parents and the  $F_1$  generation is much less than the variance of  $F_2$  generation and backcrosses. Andy et al. [18] reported that, segregation variance refers to variance due to segregation of alleles in  $F_2$  relative to variance observed in  $F_1$  from different genetic lines or divergent populations. When divergent populations are crossed, the variance of the  $F_1$  is not increased because all  $F_1$  offspring have heterozygous loci, with one allele from each divergent parent. However, an outbreak of variation is due to recombination, the "segregation variance," can often be shown in the  $F_2$  generation [19,20].

The increase in biomass, fertility, stature and other characters that led to desirable performance of the  $F_1$  progeny compared to parents refers to heterosis [21]. For variety evolution as well, selection of better combination heterosis role cannot be ignored.

**Table 5. Heritability percentage in broad ( $h^2b$ ) and narrow ( $h^2n$ ) senses and expected genetic advance from selection (GA) in the six barley crosses for all studied traits**

Results in Table 3a and b show the presence of heterotic effects compared to mid and better parents for most measured traits. This reflects that parental genotypes and F<sub>1</sub> hybrids are genetically diverse and have a wide genetic variability for the studied traits (plant height, spike length, number of grains/spike, number of spikes/plant, 100 grain weight, grain yield/plant, leaf rust and powdery mildew). Mansour [22] and El-wakeel and Hassan [23] reported significant heterosis compared to mid and better parents for grain yield and its attributes and they also reported considerable genetic variability in barley. The reduction of the mean phenotypic values which shown by traits associated with the reproductive capacity or physiological efficiency of the plant called inbreeding depression, The evaluation of inbreeding only may not be sufficient for guiding a selection program and advancing plant improvement [24]. However, despite a developed understanding of the significance of inbreeding depression, identifying specific alleles underlying the reduction in fitness has remained challenging [25].

Potence ratios could be used to set the dominance of inherited traits, with values more than  $\pm 1$  indicating over-dominance, values between  $-1$  and  $+1$  refer to partial dominance, values of  $0$  indicating no dominance and values of  $+1.0$  indicating complete dominance. The obtained results presented in Table 3a and b reflected that, partial to over-dominance were clearly involved in the inheritance of barley yield and disease severity traits. A predominance of non-additive variance components for yield related traits were found by many researchers, suggesting that heterosis could be used for breeding improvement [26,22,27].

Gene action refers to the behavior or mode of expression of genes in a genetic population. Gene action is useful to crop breeder in selection of parents for hybridization, choice of breeding methods for quantitative characters improvement and estimation of some other genetic parameters such as heritability and genetic advance from selection. Results in Table 4a and b reflecting that dominance plays greater role in inheritance of most studied traits, so selection for improvement these traits could be effective in late generations. Additive x additive gene effect was more effective than dominance x dominance and additive x dominance reflecting the important of this type of gene action, similar results were obtained by Mansour [22], Andreia et al. [24] and Attiq et al. [21]. Bojan et al. [28] reported that,

dominant was more important than additive component.

Results in Table 5 reflected high values of heritability in broad senses for all the measured traits under study. While heritability estimates in narrow sense and genetic advance from selection varied from low to moderate for the agronomic traits and low to high for disease traits. similar results were obtained by Mansour [22] and El-wakeel and Hassan [23]. Bojan et al. [28] recorded moderate to low value of narrow sense heritability for grain yield plant<sup>-1</sup>. Nikita et al. [29] observed moderate to high value of heritability accompanied by moderate to high genetic advance for grain yield and related traits. The measure of the correlation between breeding values and phenotypic values revers to heritability [30]. Thus, heritability plays a great role in crop breeding and considered as a guide to breeding value [31]. There is a direct relevance between heritability and response to the selection, which is referred to as genetic advance. High values of heritability does not necessarily mean high genetic gain and alone is not sufficient to make improvement through selection. Thus, heritability estimates utility is increased when using in estimating genetic advance [16]. High values of genetic advance correlated with high values of heritability estimates offers the most effective condition for selection [32]. The values of heritability increased when it is used to genetic advance calculating, indicating the degree of gain in a characteristic obtained under a certain selection pressure. Moreover, most agronomical important traits, including grain yield, have complex genetic inheritance and require the use of relatively large populations for studying plant breeding.

## 5. CONCLUSION

Based on the results obtained from heritability and gene action estimates it could be concluded that, this study recommended selection through the following generation in barley crosses no. 4 to improve yield potential and resistant to leaf rust and cross no. 5 to improve resistant to powdery mildew, where it had high genetic advance correlated with high heritability.
